# PERFORMANCE OF COMMERCIAL SOYBEANS IN ILLINOIS, 1982

(With 1980 and 1981 Results)

**T**HE UNIVERSITY OF ILLINOIS commercial soybean testing program was started in 1969 as a result of requests by seedsmen that their private varieties be tested. The number of individuals participating has increased each year since the start of the program.

The purpose of this commercial soybean testing program is to provide unbiased, objective, and accurate testing of all varieties entered. The tests are conducted on as uniform a soil as is available in the testing area. Small plots are used to reduce the chance of soil and climatic variations occurring between one variety plot and another.

The results of these tests should help you judge the merits of varieties in comparison with other private and public varieties. Since your soils and management may differ from those of the test location, you may wish to plant variety strips of the higher-performing varieties on your farm. The results printed in this circular should help you decide which varieties to try.

## Test Program

**Selection of entries.** Soybean producers in Illinois and surrounding states were invited to enter varieties, brands, or blends in the 1982 Illinois soybean performance trials. To help finance the testing program, a fee of \$40 (\$55 for irrigated trials) was charged for each entry entered by the seed producer. Most of these varieties, brands, or blends are commercially available, but some experimental varieties were also entered.

A total of 1,528 entries were tested in 1982.

**Number and location of tests.** In 1982, 13 major tests were conducted at 10 locations in the state (see map on page 5). These sites represent the major soils and maturity zones of the state.

**Field plot design.** Entries of each test were replicated three times in a randomized complete block or lattice design. The 30-inch-row trial plots consisted of four rows each 25 feet long. The center two rows of each plot were harvested to measure yield. The 7-inch-row trial plots consisted of ten rows each 25 feet long. The center eight rows were harvested to measure yield. All plots were end-trimmed prior to harvest.

**Fertility and weed control.** All test locations were at a high level of fertility. Herbicides were used at all test locations for weed control. All plots were also weeded by hand.

**Method of planting and harvesting.** The 30-inch row variety trials were planted with a modified bean planter. A custom-built, cone type, narrow-row drill was used to plant the 7-inch trials. Harvesting was done with a small-plot combine. No allowances were

made for beans that may have been lost as a result of combining or shattering.

## Performance Data

**Seed germination.** Two replications of each entry were planted in a greenhouse sandbench at a depth of  $\frac{1}{2}$  inch, and emergence percentages were recorded after 7 days. This test measured the ability of the soybean varieties to germinate and emerge under ideal conditions.

**Seedling emergence.** The emergence score, which is related to hypocotyl elongation, measures the ability of soybean seed to germinate and emerge when planted too deep in the field. Three replications of each brand, variety, or blend entered were planted in sand at a depth of  $3\frac{1}{2}$  inches. Temperature was held constant at 25° C. for the duration of the test. Emergence scores were measured as the percentage of seeds that germinated and emerged 8 days after planting. The following scores were used to compare entries:

- 1 — 80% or more emerged
- 2 — 70 to 79% emerged
- 3 — 40 to 69% emerged
- 4 — 20 to 39% emerged
- 5 — 0 to 19% emerged

**Yield.** Soybean yield was measured in bushels (60 pounds) per acre at a moisture content of 12.5 percent. An electronic moisture monitor was used on the combine for all moisture readings.

**Maturity.** Maturity was stated as the date when approximately 95 percent of the pods were ripe.

**Lodging.** The amount of lodging was rated at harvesttime. The following scale was used:

- 1 — Almost all plants erect
- 2 — All plants leaning slightly or a few plants down
- 3 — All plants leaning moderately (45°), or 25 to 50 percent of the plants down
- 4 — All plants leaning considerably, or 50 to 80 percent of the plants down
- 5 — Almost all plants down

**Height.** Height was measured shortly before harvest as the average length of plants from the ground to the tip of the main stem.

**Shattering.** The percentage of open pods was estimated at harvesttime. The following scale was used:

- 1 — No shattering
- 2 — 1 to 10% of pods open
- 3 — 10 to 25% of pods open
- 4 — 25 to 50% of pods open
- 5 — Over 50% of pods open

## Suggestions for Comparing Entries

It is impossible to obtain an exact measure of performance when conducting any test of plant material. Harvesting efficiency may vary, soils may not be uniform, and many other conditions may produce variability. Results of repeated tests are more reliable than those of a single year or a single strip test. When one variety consistently outyields another at several test locations and over several years of testing, the chances are good that this difference is real and should be considered in selecting a variety. However, yield is not the only indicator. You should also consider maturity, lodging, and germination.

As an aid in comparing soybean varieties, brands, and blends within a single trial, certain statistical tests have been devised. One of these tests, the least significant difference (L.S.D.), when used in the manner suggested by Carmer and Swanson,<sup>1</sup> is quite simple to apply and is more appropriate than most other tests. When two entries are compared and the difference between them is greater than the tabulated L.S.D. value, the entries are judged to be "significantly different."

When the observed mean of entry A is larger than that of entry B and the difference between them is found to be significant, then either (1) the mean of entry A really is larger than that of entry B, and a correct decision has been made; (2) the means of entries A and B are really equal, and a Type I statistical error has been made (that is, the means were declared to be unequal when they were actually equal); or (3) the mean of entry B is really larger than that of entry A, and a reverse decision or Type II statistical error has been made (that is, the mean of A was declared to be greater than that of B, when the reverse is true).

When no significant difference is found between two entries, then either (1) the means are really equal and a correct decision has been made; or (2) the means are really different, and a Type II statistical error has been made (that is, the means were declared to be equal when they really are different). In a study of the frequencies of occurrence of these three types of statistical errors and their relative seriousness, Carmer<sup>2</sup> found strong arguments for an optimal significance level in the range  $\alpha = 0.20$  to  $0.40$ , where  $\alpha$  is the Type I statistical error rate for comparisons between means that are really equal. Herein, values of  $\alpha = 0.10$  and  $0.30$  are used in computing the L.S.D. 10- and 30-percent levels shown in the tables.

To make the best use of the information presented in this circular and to avoid any misunderstanding or misrepresentation of it, the reader should consider an additional caution about comparing entries. Readers who compare entries in different trials should be ex-

remely careful, since no statistical tests are presented for that purpose. Readers should note that the difference between a single entry's performance at one location and its performance at another is caused primarily by environmental effects and random variability. Furthermore, the difference between the performance of entry A in one trial and the performance of entry B in another is the result not only of environmental effects and random variability, but of genetic effects as well.

## 1982 Test Fields

### DeKalb

Location: University of Illinois Northern Illinois Research Center, southwest of DeKalb.

Soil type: Flanagan silt loam (dark brown, adequately drained, highly fertile).

Cooperators: R.R. Bell, field manager; D.L. Mulvaney, research director.

Planting date: May 19.

Harvest dates: October 14 and 15.

### Elwood

Location: Northeastern Illinois Agronomy Center, Will County.

Soil type: Elliott silt loam.

Cooperators: Dale Harshbarger, field manager; D.L. Mulvaney, research director.

Planting date: May 25.

Harvest dates: October 26 and 27.

<sup>1</sup> Carmer, S. G. and M. R. Swanson. An Evaluation of Ten Pairwise Multiple Comparison Procedures by Monte Carlo Methods. *Journal of American Statistical Association* 68:66-74, 1973.

<sup>2</sup> Carmer, S. G. Optimal Significance Levels for Application of the Least Significant Difference in Crop Performance Trials. *Crop Science* 16:95-99, 1976.

### Monmouth

Location: University of Illinois Northwestern Illinois Agricultural Research and Demonstration Center, northwest of Monmouth.

Soil type: Muscatine silt loam.

Cooperators: Mike Mainz, area agronomist and field superintendent; Jay Sutor, farm foreman.

Planting date: May 18.

Harvest dates: October 5 and November 16.

Comments: Heavy rains during July resulted in excessive vegetative growth and early lodging of many entries.

### Kilbourne (Irrigated)

Location: University of Illinois Illinois River Valley Sand Field, 10 miles west of Kilbourne, Mason County, central Illinois.

Soil type: Plainfield sand.

Cooperators: H. Hopen, research director; LaVern Hahn, superintendent.

Planting date: May 12.

Harvest date: October 11.

Irrigation: A total of 10.15 inches of water was applied in 11 applications during the growing season to supplement natural rainfall.

Comments: Many plots were physically damaged by equipment used in a postemergence herbicide application.

### Urbana

Location: University of Illinois South Farm, Champaign County, east central Illinois.

Soil type: Flanagan silt loam (dark brown, adequately drained).

Cooperators: M.G. Oldham, farm manager; Mike Plotner, farm foreman.

Planting date: May 11.

Harvest dates: September 23, 24, and 29, and October 12, 16, and 28.

### Perry

Location: Orr Research Center, near Perry, Pike County, south central Illinois.

Soil type: Herrick silt loam (moderately poorly drained).

Cooperators: Glenn Raines, research director; Tom Hallock, field superintendent.

Planting date: May 13.

Harvest date: October 18.

Comments: Emergence was erratic and stands were only fair. Weeds were a problem throughout the growing season.

### Brownstown

Location: University of Illinois Brownstown Experimental Field, Fayette County, south central Illinois.

Soil type: Cisne silt loam (poorly drained, gray prairie with a well-developed claypan).

Cooperator: Frank Zajicek, research director.

Planting date: May 14.

Harvest dates: September 30 and October 25.

### Belleville

Location: Southern Illinois University Research Center, east of Belleville, St. Clair County.

Soil type: Ebbert silt loam.

Cooperators: Chuck Strieker, field manager; George Kapusta, agronomist.

Planting date: May 20.

Harvest date: October 22.

### Carbondale

Location: Southern Illinois University Agronomy Research Center, extreme southern Illinois.

Soil type: Weir silt loam (shallow, silty loam over claypan).

Cooperators: Jim Hubbard, field manager; George Kapusta, agronomist.

Planting date: May 20.

Harvest date: October 20.

Comments: Heavy infestations of soybean cyst nematodes severely stunted all susceptible entries.

### Dixon Springs

Location: University of Illinois Dixon Springs Agricultural Center, Pope County, extreme southern Illinois.

Soil type: Sharon silt loam (light-colored, moderately well drained, medium-textured bottomland).

Cooperator: George McKibben, professor.

Planting date: May 21.

Harvest date: October 20.

Comments: Stands were extremely poor in the group V maturity test. Caution should be used in comparing these entries.

### Growing Season Rainfall

Location	May	June	July	August
DeKalb	3.97	4.32	6.48	1.52
